

Survey Development Framework

Wenchao Ma
University of Minnesota

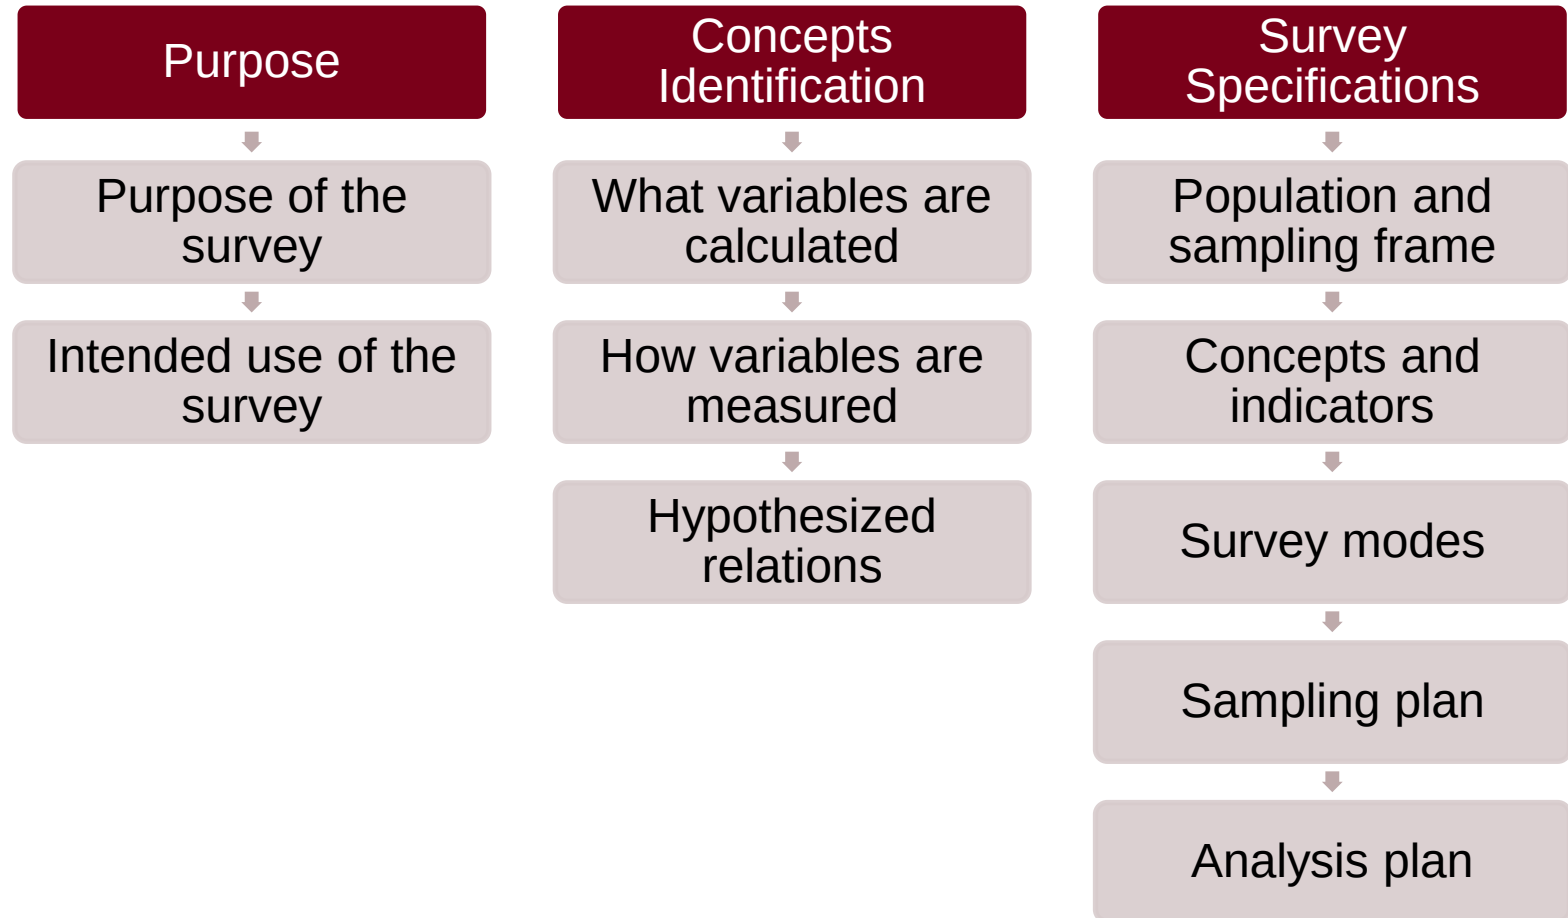

Survey Development Framework

1. Survey design
2. Survey construction
3. Pilot testing
4. Survey administration

1. Survey Design

1. Survey Design

- Key questions to be answered during survey design
 - What are the target concepts that are being measured?
 - What are the structures of the target concepts (factors, components, subconstructs, subdomains)?
 - How can the concepts be measured reliably and validly?
 - What are the survey research questions?
 - How can those concepts be analyzed to answer the survey questions?

2. Survey construction

- Item and instruction writing
 - Do you use an existing scale or develop new questions?
 - How many questions should be used for measuring each concept?
- Survey formatting
 - Depends on the survey modes

3. Pilot Testing

Pretesting

- Expert review
- Cognitive interview

Pilot test

- Pretest a small sample
- Calculate reliability
- Find item quality statistics

Field testing

- Larger sample
- Reliability estimates
- Validity evidence
- Item quality evidence

Pre-testing

- Survey researchers have shown remarkable confidence in pre-testing.
- According to one leading expert, “It usually takes no more than 12–25 cases to reveal the major difficulties and weaknesses in a pretest questionnaire” (Sheatsley 1983, p. 226).
- This judgment is similar to that of another prominent methodologist, who maintained that “20–50 cases is usually sufficient to discover the major flaws in a questionnaire” (Sudman 1983, p. 181).

4. Survey Administration
